Selection based on expected values

- **Until now:** The optimal action choice was the option that maximized the expected monetary value.
- But is the expected monetary value always the quantity we want to optimize?

Selection based on expected values

- Is the expected monetary value always the quantity we want to optimize?
- **Answer:** Yes, but only if we are risk-neutral.
- But what if we do not like the risk (we are risk-averse)?
- In that case we may want to get the premium for undertaking the risk (of loosing the money)
- Example:
 - we may prefer to get \$101 for sure against \$102 in expectation but with the risk of loosing the money
- Problem: How to model decisions and account for the risk?
- Solution: use utility function, and utility theory

CS 2710 Foundations of AI

Utility function

- Utility function (denoted U)
 - Quantifies how we "value" outcomes, i.e., it reflects our preferences
 - Can be also applied to "value" outcomes other than money and gains (e.g. utility of a patient being healthy, or ill)
- Decision making:
 - uses expected utilities (denoted EU)

$$EU(X) = \sum_{x \in \Omega_X} P(X = x)U(X = x)$$

U(X = x) the utility of outcome x

Important!!!

 Under some conditions on preferences we can always design the utility function that fits our preferences

Utility theory

- Defines **axioms on preferences** that involve uncertainty and ways to manipulate them.
- Uncertainty is modeled through **lotteries**
 - Lottery:

$$[p:A;(1-p):C]$$

- Outcome A with probability p
- Outcome C with probability (1-p)
- The following six constraints are known as the axioms of utility theory. The axioms are the most obvious semantic constraints on preferences with lotteries.
- Notation:

> - preferable

~ - indifferent (equally preferable)

CS 2710 Foundations of AI

Axioms of the utility theory

• Orderability: Given any two states, a rational agent prefers one of them, else the two as equally preferable.

$$(A \succ B) \lor (B \succ A) \lor (A \sim B)$$

• Transitivity: Given any three states, if an agent prefers A to B and prefers B to C, agent must prefer A to C.

$$(A \succ B) \land (B \succ C) \Rightarrow (A \succ C)$$

• Continuity: If some state *B* is between *A* and C in preference, then there is a *p* for which the rational agent will be indifferent between state B and the lottery in which A comes with probability p, C with probability (1-p).

$$(A \succ B \succ C) \Rightarrow \exists p [p : A; (1-p) : C] \sim B$$

Axioms of the utility theory

• Substitutability: If an agent is indifferent between two lotteries, A and B, then there is a more complex lottery in which A can be substituted with B.

$$(A \sim B) \Rightarrow [p:A;(1-p):C] \sim [p:B;(1-p):C]$$

 Monotonicity: If an agent prefers A to B, then the agent must prefer the lottery in which A occurs with a higher probability

$$(A \succ B) \Rightarrow (p > q \Leftrightarrow [p : A; (1-p) : B] \succ [q : A; (1-q) : B])$$

• **Decomposability:** Compound lotteries can be reduced to simpler lotteries using the laws of probability.

$$[p:A;(1-p):[q:B;(1-q):C]] \Rightarrow$$

 $[p:A;(1-p)q:B;(1-p)(1-q):C]$

CS 2710 Foundations of AI

Utility theory

If the agent obeys the axioms of the utility theory, then

1. there exists a real valued function U such that:

$$U(A) > U(B) \Leftrightarrow A \succ B$$

 $U(A) = U(B) \Leftrightarrow A \sim B$

2. The utility of the lottery is the expected utility, that is the sum of utilities of outcomes weighted by their probability

$$U[p:A;(1-p):B] = pU(A) + (1-p)U(B)$$

3. Rational agent makes the decisions in the presence of uncertainty by maximizing its expected utility

Utility functions

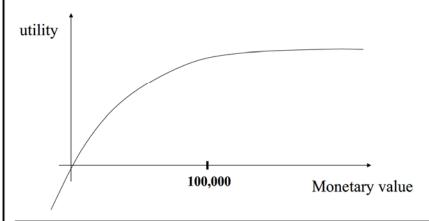

We can design a utility function that fits our preferences if they satisfy the axioms of utility theory.

- But how to design the utility function for monetary values so that they incorporate the risk?
- What is the relation between the utility function and monetary values?
- Assume we loose or gain \$1000.
 - Typically this difference is more significant for lower values (around \$100 -1000) than for higher values (~ \$1,000,000)
- What is the relation between utilities and monetary value for a typical person?

CS 2710 Foundations of AI

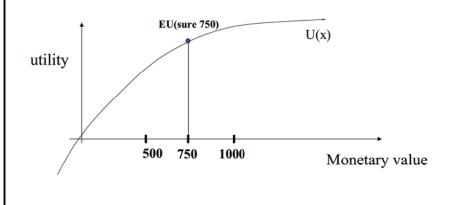

Utility functions

- What is the relation between utilities and monetary value for a typical person?
- Concave function that flattens at higher monetary values

Utility functions

• Expected utility of a sure outcome of 750 is 750

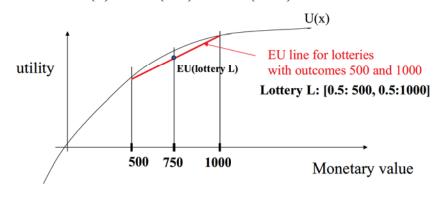

CS 2710 Foundations of AI

Utility functions

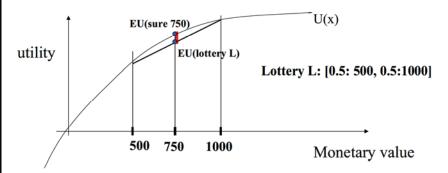

Assume a lottery L [0.5: 500, 0.5:1000]

- Expected value of the lottery = 750
- Expected utility of the lottery EU(L) is different:
 - EU(L) = 0.5U(500) + 0.5*U(1000)

Utility functions

• Expected utility of the lottery EU(lottery L) < EU(sure 750)

• Risk aversion – a bonus is required for undertaking the risk
