## Machine Learning

- The field of **machine learning** studies the design of computer programs (agents) capable of learning from past experience or adapting to changes in the environment
- The need for building agents capable of learning is everywhere
  - Predictions in medicine, text classification, speech recognition, image/text retrieval, commercial software
- Machine learning is not only the deduction but induction of rules from examples that facilitate prediction and decision making

---

CS 2710 Foundations of AI

# Learning

## Learning process:

Learner (a computer program) takes data  $D$  representing past experiences and tries to either:

- to develop an appropriate response to future data, or
- describe in some meaningful way the data seen

## Example:

Learner sees a set of past patient cases (patient records) with corresponding diagnoses. It can either try:

- to predict the presence of a disease for future patients
- describe the dependencies between diseases, symptoms (e.g. builds a Bayesian network for them)

# Types of learning

- **Supervised learning**
  - Learning mapping between inputs  $x$  and desired outputs  $y$
  - Teacher gives me  $y$ 's for the learning purposes
- **Unsupervised learning**
  - Learning relations between data components
  - No specific outputs given by a teacher
- **Reinforcement learning**
  - Learning mapping between inputs  $x$  and desired outputs  $y$
  - Critic does not give me  $y$ 's but instead a signal (reinforcement) of how good my answer was
- **Other types of learning:**
  - **Concept learning, explanation-based learning, etc.**

## Supervised learning

**Data:**  $D = \{d_1, d_2, \dots, d_n\}$  a set of  $n$  examples

$$d_i = \langle \mathbf{x}_i, y_i \rangle$$

$\mathbf{x}_i$  is input vector, and  $y$  is desired output (given by a teacher)

**Objective:** learn the mapping  $f : X \rightarrow Y$

$$\text{s.t. } y_i \approx f(x_i) \text{ for all } i = 1, \dots, n$$

**Two types of problems:**

- **Regression:**  $X$  discrete or continuous  $\rightarrow$   
 $Y$  is **continuous**
- **Classification:**  $X$  discrete or continuous  $\rightarrow$   
 $Y$  is **discrete**

## Supervised learning examples

- **Regression:**  $Y$  is **continuous**

- **Classification:**  $Y$  is **discrete**

Handwritten digit (array of 0,1s)

## Unsupervised learning

- **Data:**  $D = \{d_1, d_2, \dots, d_n\}$   
 $d_i = \mathbf{x}_i$  vector of values  
No target value (output)  $y$
- **Objective:**
  - learn relations between samples, components of samples

### Types of problems:

- **Clustering**
  - Group together “similar” examples, e.g. patient cases
- **Density estimation**
  - Model probabilistically the population of samples, e.g. relations between the diseases, symptoms, lab tests etc.

## Unsupervised learning example.

- **Density estimation.** We want to build the probability model of a population from which we draw samples  $d_i = \mathbf{x}_i$

## Unsupervised learning. Density estimation

- A probability density of a point in the two dimensional space
  - Model used here: Mixture of Gaussians

CS 2710 Foundations of AI

## Reinforcement learning

- We want to learn:  $f : X \rightarrow Y$
- We see samples of  $x$  but not  $y$
- Instead of  $y$  we get a feedback (reinforcement) from a **critic** about how good our output was

- The goal is to select output that leads to the best reinforcement

CS 2710 Foundations of AI

## Learning

- Assume we see examples of pairs  $(x, y)$  and we want to learn the mapping  $f : X \rightarrow Y$  to predict future  $y$ s for values of  $x$
- We get the data what should we do?

CS 2710 Foundations of AI

## Learning bias

- **Problem:** many possible functions  $f : X \rightarrow Y$  exists for representing the mapping between  $x$  and  $y$
- Which one to choose? Many examples still unseen!

CS 2710 Foundations of AI

## Learning bias

- Problem is easier when we make an assumption about the model, say,  $f(x) = ax + b$
- Restriction to a linear model is an example of the learning bias

CS 2710 Foundations of AI

## Learning bias

- **Bias** provides the learner with some basis for choosing among possible representations of the function.
- **Forms of bias:** constraints, restrictions, model preferences
- **Important:** There is no learning without a bias!

CS 2710 Foundations of AI

## Learning bias

- Choosing a parametric model or a set of models is not enough  
Still too many functions  $f(x) = ax + b$ 
  - One for every pair of parameters  $a, b$

CS 2710 Foundations of AI

## Fitting the data to the model

We are interested in finding the **best set** of model parameters

**How is the best set defined?**

Our goal is to have the parameters that:

- reduce the misfit between the model and data
- Or, (in other words) that explain the data the best

**Error function:**

**Gives a measure of misfit between the data and the model**

- Examples of error functions:

- Mean square error 
$$\frac{1}{n} \sum_{i=1}^n (y_i - f(x_i))^2$$

- Misclassification error

Average # of misclassified cases  $y_i \neq f(x_i)$

CS 2710 Foundations of AI

## Fitting the data to the model

- **Linear regression**

- Least squares fit with the linear model

- minimizes  $\frac{1}{n} \sum_{i=1}^n (y_i - f(x_i))^2$

CS 2710 Foundations of AI

## Typical learning

### Three basic steps:

- **Select a model** or a set of models (with parameters)

E.g.  $y = ax + b$

- **Select the error function** to be optimized

E.g.  $\frac{1}{n} \sum_{i=1}^n (y_i - f(x_i))^2$

- **Find the set of parameters optimizing the error function**

- The model and parameters with the smallest error represent the best fit of the model to the data

But there are problems one must be careful about ...
