

Gambling example
RL model:
- Input: X – a coin chosen for the next toss,
- Action: A – choice of head or tail,
– Reinforcements: {1, -1}
- A policy π : Coin1 \rightarrow head Coin2 \rightarrow tail Coin3 \rightarrow head
• Learning goal: find $\pi: X \to A$ $\pi: \begin{bmatrix} \operatorname{Coin1} \to ? \\ \operatorname{Coin2} \to ? \\ \operatorname{Coin3} \to ? \end{bmatrix}$
maximizing future expected profits
$E(\sum_{t=0}^{\infty} \gamma^{t} r_{t}) = \gamma$ a discount factor = present value of money

Model free learning• Motivation: value function update (value iteration): $V(s) \leftarrow \max_{a \in A} \left[R(s, a) + \gamma \sum_{s' \in S} P(s' | s, a) V(s') \right]$ • Let $Q(s, a) = R(s, a) + \gamma \sum_{s' \in S} P(s' | s, a) V(s')$ • Then $V(s) \leftarrow \max_{a \in A} Q(s, a)$ • Note that the update can be defined purely in terms of Q-functions $Q(s, a) \leftarrow R(s, a) + \gamma \sum_{s' \in S} P(s' | s, a) \max_{a'} Q(s', a')$
